## 1 Abstract

State machine algorithms for aligning Nanopore reads. Initial goal is simple reusable code for aligning a nanopore read to a reference sequence. No attempt at optimization yet.

## 2 Specification

### 2.1 Parameterization algorithm

Given the following inputs

- Reference genome (FASTA)
- Segment-called reads (FAST5/HDF5)

Perform the following steps

- Perform Baum-Welch to fit a rich model

Rich model incorporates segment statistics.

### 2.2 Reference search algorithm

Given the following inputs

- Reference genome
- Segment-called reads (FAST5/HDF5)
- Parameterized rich model

Perform the following steps

- Perform Viterbi alignment

## 2.3 Implementation

Libraries etc.

HDF5...

## 2.4 Evaluation

Strategy...

Data sets...

# 3 Methods

Model & inference algorithms.

## 3.1 Model

- Order- $N$  transducer.
- Input: nucleotide
- Output: nucleotide, segment mean, duration
- Emissions:
  - categorical (base  $k$ -mer)
  - mixture of Normal/gamma (mean/duration)
- Transitions:
  - *Match*: emit single segment, absorb 1 base
  - *Insert*: affine gap insertion of bases: emits segments, absorbs no bases
  - *Delete*: affine gap deletion of bases: emits no segments, absorbs bases
  - *Merge*: emit single segment, absorb 2 or 3 bases

- *Split*: emit single segment, absorb 0 bases
- *Skip*: emit single segment, absorb  $2 \dots K$  bases (large  $K$ , low extension penalty)

This can be achieved by a Mealy transducer with  $3 \times 4^N$  states. The factor of  $4^N$  accounts for the order- $N$  context. For each such context, the three states are MAT, INS and DEL.

Parameters:

- Gap opening & extension probabilities  $\lambda_{go}, \lambda_{gx}$
- Merge probability  $\lambda_{mo}$ , probability that it's a 3-merge is  $\lambda_{mx}$
- Split probability  $\lambda_s$
- Skip probability  $\lambda_{ko}$ , skip extension probability  $\lambda_{kx}$

In general the emissions are of the form

$$(y, m, d) \sim \text{CNG}(L)$$

where  $L$  is a “label”

$$y \sim \text{Categorical}(\mathbf{p}_L)$$

$$m \sim \text{Normal}(\mu_L, \tau_L)$$

$$d \sim \text{Gamma}(\alpha_L, \beta_L)$$

The transition table is as follows:

Transition	From	To	Weight	Input	Output
Match	MAT	MAT	$(1 - \lambda_{go})(1 - \lambda_{mo})(1 - \lambda_s)(1 - \lambda_{ko})$	$x \in \Omega$	$(y, m, d) \sim \text{CNG}(\text{match}, x, c)$
Insert	MAT	INS	$\lambda_{go}/2$		
	INS	INS	$\lambda_{gx}$		
	INS	MAT	$1 - \lambda_{gx}$	none	none
Delete	MAT	DEL	$\lambda_{go}/2$		
	DEL	DEL	$\lambda_{gx}$		
	DEL	MAT	$1 - \lambda_{gx}$	none	none
Merge	MAT	MAT			
Split	MAT	MAT			
Skip	MAT	MAT			

Here  $y \in \Omega$  where  $\Omega$  is the nucleotide alphabet and  $c \in \Omega^N$  is the context.

### 3.2 Baum-Welch algorithm

### 3.3 Viterbi algorithm

## 4 Results

## 5 Discussion

## **6 Acknowledgments**

## **7 Figure Legends**

## 8 Appendix

### 8.1 Gamma distribution

$$x \sim \text{Gamma}(\alpha, \beta)$$

$$\mathbb{E}[x] = \alpha/\beta$$

$$\text{Var}[x] = \alpha/\beta^2$$

Shape parameter  $\alpha$ , rate parameter  $\beta$ .

$$P(x|\alpha, \beta) = \frac{x^{\alpha-1} \beta^\alpha \exp(-x\beta)}{\Gamma(\alpha)}$$

where  $\Gamma$  is the gamma function

$$\Gamma(\alpha) = \int_0^\infty z^{\alpha-1} \exp(-z) dz$$

Note  $\Gamma(n) = (n-1)!$  for positive integer  $n$ .

### 8.2 Normal distribution

$$x \sim \text{Normal}(\mu, \tau)$$

Mean  $\mu$ , precision  $\tau$  (precision is reciprocal of variance).

$$P(x|\mu, \tau) = \sqrt{\frac{\tau}{2\pi}} \exp\left(-\frac{\tau}{2}(x-\mu)^2\right)$$
